

**California Department of Fish and Game (CDFG) Alternative (Alternative 5) Evaluation Conducted by  
Dr. Sabrina Cook (PBS&J) in Support of Responses to Comments on the El Sur Water Right Application  
No. 30166 Draft EIR**

**October 10, 2010**

The potential effects of the CDFG Alternative were analyzed for limiting flow conditions. Records of daily flow rates at the USGS gauge for the baseline period of record were assessed to determine when and how often the CDFG Alternative limiting conditions (bypass flows) occurred. If flow did not exceed the CDFG Alternative bypass flow requirements, diversions could not occur. If flow did exceed the CDFG Alternative bypass flow requirements, diversions were assumed to occur at the maximum allowable diversion rate (2.79 cfs). These were compared with baseline diversion records and proposed project application diversion requests. Effects of diversion limits for DO and salinity conditions could not be analyzed because sufficient long term records for these parameters do not exist.

Table A5-1 shows the number of days in each month that diversions would be allowed under the CDFG Alternative (days with flow at the USGS gauge greater than 40 cfs from June through November and greater than 132 cfs from December through May). On average, pumping would be allowed during less than 20 percent of the year. From June through October, when irrigation is critical no pumping would be allowed for the entire season during 45 percent of years and overall, only 9 percent of days would pumping be allowed. From July through October, the Water Rights Application irrigation season, 60 percent of the time no irrigation would be allowed under the CDFG Alternative.

Table A5-2 shows the CDFG Alternative potential diversions based on the number of days diversions would be allowed and the diversion rate of 2.79 cfs, with an overall annual maximum cap of 557.5 AF. Table A5-3 compares the CDFG Alternative diversions with calculated required diversions for optimum pasture growth (Table 2-3 of the DEIR). Negative values (in parenthesis) indicated an irrigation deficit compared to the required irrigation. Overall, the CDFG Alternative would not meet required irrigation amounts

Table A5-4 compares the CDFG Alternative to the proposed project. No reasonable comparison for winter months is feasible because the Water Rights Application does not provide sufficient detail. However, the critical irrigation and flow conditions are during the dry weather season and these months are presented in Table A5-4. Generally, the CDFG Alternative would substantially reduce diversions during the dry season compared to the maximum monthly, maximum irrigation season, and 20-year rolling average proposed project diversion. This is primarily because no diversions would be allowed during the majority of the dry season (Table A5-1).

The CDFG Alternative would also typically substantially reduce diversions compared to baseline conditions for most dry season months and on an annual basis. However, wet season diversions could increase compared to baseline. Refer to Tables A5-5(a) and A5-5(b).

Table A5-1 Number of Days Irrigation Diversions Allowed By the CDFG Alternative

(x) = deficit, negative number

## Water Surface Elevation

Water surface elevation effects were calculated based on the relationship of 0.33-inch reduction in water surface elevation within the ZOI per cfs pumped. This relationship was developed from SGI 2007 Study piezometer data. Table A5-1 shows the number of days pumping could occur during each month for each year under the CDFG Alternative. Months where pumping could occur for at least one day under the CDFG Alternative are highlighted in blue. No highlight indicates pumping would not be allowed under the CDFG Alternative. Assuming the maximum pumping rate allowed under the CDFG Alternative (2.79 cfs), Table A5-6 shows the potential effect on water surface elevation compared to baseline. A positive number indicates that the CDFG Alternative would have a higher water surface elevation compared to baseline. A negative number, numbers within parenthesis, indicates the CDFG Alternative would contribute to a lower water surface elevation compared to baseline.

Diversion allowed at least one day for Alt 5						
(x) = negative number; CDFG Alternative results in lower water surface elevation compared to baseline						

In Table A5-6, it is evident that the CDFG Alternative would typically reduce potential effects on water surface elevations compared to baseline (up to 1.49 inches), but this effect is mostly attributed to the limitation that no pumping would be allowed under most conditions in the dry season. In some years,

when the CDFG Alternative would allow pumping, the CDFG Alternative contributes to a greater reduction in water surface elevation (negative number) compared to baseline. During November, when baseline pumping is minimal, under the CDFG Alternative, higher pumping rates could also contribute to lower water surface elevation than baseline conditions.

Compared to the proposed project, the CDFG Alternative would reduce dry season effects on water surface elevations by 0.99 inches on average (average monthly July through October diversion), and up to 1.76 inches (maximum sustained 30-day average) during conditions when the CDFG Alternative would not allow pumping because of bypass flow criteria. During conditions where pumping would be allowed, the CDFG Alternative would improve water surface elevations during sustained maximum pumping conditions (0.84 inches) and only slightly during average July through October months (0.07 inches).
